
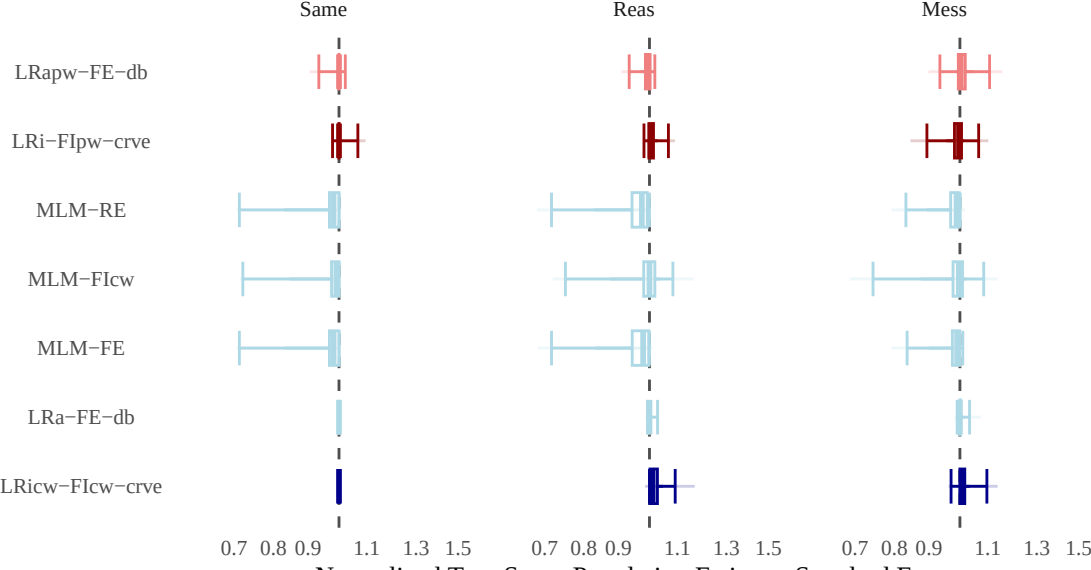

Figure 4: Boxplot of normalized estimate true standard errors across the different scenarios by method. The normalized true standard error is the true standard error for a given method divided by the median true standard error across methods within a given simulation scenario. Therefore each data point is adjusted for the underlying base true standard error from a given set of DGPs and represents the true standard error driven by the estimation method. The faint horizontal lines extend to the full range, the bars span the 2.5th to 97.5th percentiles, and the boxes span the 10th to 90th percentiles.
